-

Overview

The CPU is the heart of the control system. Almost all system operations are controlled by the CPU, so it is very important to set up and install it correctly. This chapter provides the information needed to understand:

- the differences between the various models of CPUs
- the steps required to setup and install the CPU

General CPU Features

The DL430, DL440, and DL450 are all modular CPUs which are installed in either 4, 6, or 8 slot bases. All I/O modules in the DL405 family will work with either CPU. The DL405 CPUs offer a wide range of processing power and program instructions. All offer RLL and Stage program instructions (See Chapter 5 for instruction definitions). All DL405 CPUs have extensive internal diagnostics that can be monitored from the application program or from an operator interface.

The three standard CPU types accept either 110VAC or 220 VAC for power input. The DL440 CPU is available in two additional DC versions: the DL440DC-1 uses 24 VDC, and the DL440DC-2 uses 125 VDC.

DL430 CPU Features

The DL430 has 6.5K of program memory comprised of 3.5K of ladder memory and 3K of V-memory (data registers). It has 113 instructions available for program development, and supports a maximum of 640 points of local and local expansion I/O and 512 points of remote I/O.

Program storage is in the EEPROM which is built into the CPU. In addition to the EEPROM there is also RAM on the CPU which will store system parameters, V-memory and other data which is not in the application program.

The DL430 provides two built-in communications ports. The first has a RS232C interface and the other has a RS232C/RS422 interface. This allows for a point-to-point connection on the first port and the option of either a multidrop network connection (such as **DirectNET**) or a point-to-point connection on the other port.

DL440 CPU Features

The DL440 includes all the DL430 features, plus more I/O points, more program instructions, and greater memory space with plug-in memory cartridges. It has a maximum of 22.5K of program memory comprised of 15.5K of ladder memory and 7K of V-memory (data registers). It supports a maximum of 640 points of local and local expansion I/O and 1024 points of remote I/O. Its two communications ports operate identically to the DL430's ports.

The DL440 has 170 instructions. The additional 57 instructions to the DL430 instruction set allow for more sophisticated program development through the use of subroutines, additional instructions that support double word manipulation, enhanced stack operations, diagnostic messaging, and ASCII/Hex data formatting.

DL450 CPU Features

The new DL450 offers all the DL440 features, plus more I/O points, program instructions, and two additional (4 total) communications ports. It has a maximum of 30.8K of program memory comprised of 15.5K of ladder memory and 15.3K of V-memory (data registers). It supports a maximum of 2048 points of local and local expansion I/O, and 1536 points of remote I/O. It includes an additional internal RISC-based microprocessor for greater processing power. The DL450 has 210 instructions. The additional 40 instructions to the DL440 instruction set include drum timers, a print function, floating point math, trigonometric functions, and PID loop control for 16 loops.

The DL450 has a total of four communications ports. The first two ports are identical to those on the DL430 and DL440. The third port has a RS-232C interface and can be configured for either N sequence or K sequence protocol. It uses a modular connector for point-to-point communications to devices such as the DV-1000 Data Access Unit. The fourth port has a RS-422 interface using either MODBUS master/slave, N sequence, or K sequence protocol. These four ports utilize three physical connectors (the bottom connector has two ports on the DL450).

CPU General Specifications

Features	DL430	DL440	DL450
Total Program memory (words)	6.5K	14.5K / 22.5K*	22.8K / 30.8K*
Ladder memory (words), built-in	3.5K	7.5K / 15.5K*	7.5K / 15.5K*
V-memory (words)	3.0K	7.0K	15.3K
Scan Time, typical (1 K boolean)	8 – 10 mS	2 – 3 mS	4 – 5 mS
Run time edit	No	Yes	Yes
RLL and RLL <i>PLUS</i> Programming	Yes	Yes	Yes
Handheld programmer with cassette tape interface	Yes	Yes	Yes
Direct SOFT32 programming for Windows™	Yes	Yes	Yes
Built-in communication ports	2 ports	2 ports	4 ports
CMOS RAM	No	w/mem. cartridge	w/mem. cartridge
UVPROM	No	w/mem. cartridge	w/mem. cartridge
EEPROM	Standard on CPU	w/mem. cartridge	w/mem. cartridge
FLASH RAM	No	No	Standard on CPU
Compatible with:			
CoProcessor™ modules	Yes	Yes	Yes
Networking modules	Yes	Yes	Yes
RS232C/RS422 Data Comm. Module	Yes	Yes	Yes
Total I/O	1152	1664	3584
Total I/O available as:			
Local I/O / Local expansion I/O / Remote I/O	640	640	4096
Remote I/O	512 max.	1024 max.	2048 max.
Remote I/O Channels	2	2	3
Local discrete input points maximum	320	320	1024
Local discrete output points maximum	320	320	1024
Local analog input channels maximum	320**	320**	512**
Local analog output channels maximum	320**	320**	512**
Maximum number of channels / masters (remote or slice) per local CPU base	2	2	2
Remote I/O Distance	3300 ft. (1000m)	3300 ft. (1000m)	3300 ft. (1000m)
Discrete I/O Module Point Density	8/16/32/64	8/16/32/64	8/16/32/64
Slots per Base	4/6/8	4/6/8	4/6/8

* The first values represent CPUs using the 7.5K memory cartridge and the second value is for using 15.5K memory cartridges.

** Additional Discrete and Analog I/O can be supported (within the power budget) through the use of remote I/O.

Feature	DL430	DL440	DL450
Number of instructions available (see Chapter 5 for a description of the available instructions)	113	170	210
Control relays	480	1024	2048
Special relays (system defined)	288	352	512
Stages in RLL <i>PLUS</i>	384	1024	1024
V-memory	3072 words	7168 words	15360 words
Timers	128	256	256
Counters	128	128	256
Immediate I/O	Yes	Yes	Yes
Interrupt input	8 points	16 points	16 points
Subroutines	No	Yes	Yes
For/Next Loops	No	Yes	Yes
Drum Timers	No	No	Yes
Math	Integer	Integer	Integer and Floating Point
PID Loop Control, built-in	No	No	16 loops
Time of Day Clock/Calendar	No	Yes	Yes
Internal diagnostics	Yes	Yes	Yes
Password security	No	Yes	Yes, multi-level
System and user error log	No	Yes	Yes
Battery backup	Yes	Yes	Yes

CPU Electrical Specifications

Parameter	DL430/DL440/DL450	DL440/450DC-1	DL440/450DC-2
Input Voltage, Nominal	120 VAC	24 VDC	125 VDC
Input Voltage Range	100–120 VAC and 196–240 VAC +10% –15%	20–29 VDC	100–132 VDC +10% –15%
Input Voltage Ripple	N/A	less than 10%	less than 10%
Inrush Current, maximum	20 A	10 A	20 A
Power Consumption, maximum	50 VA	38W	30 W
Voltage withstand (dielectric strength)	1 min. at 1500 VAC between primary, secondary, field ground and run relay		
Insulation resistance	> 10M Ω at 500 VDC		
Output Voltage, auxiliary power supply	20–28 VDC (24 nominal), ripple more than 1V P-P (N/A on DL440–DC-1 and DL440-2)		
Output Current, auxiliary power supply	24 VDC @ 400 mA maximum		

CPU Hardware Features

The following diagram shows the main external features of the DL405 CPUs.

DL430/DL440 CPUs

DL450 CPU

Keyswitch Functions

The keyswitch on the DL405 CPUs provides positions for enabling and disabling program changes in the CPU. Unless the keyswitch is in the TERM position, RUN and STOP mode changes will not be allowed by any interface device, (handheld programmer, **DirectSOFT32** programming package or operator interface). Programs may be viewed or monitored but no changes may be made. If the switch is in the TERM position and no program password is in effect, all operating modes as well as program access will be allowed through the connected programming or monitoring device.

Keyswitch Position	CPU Action
RUN (Run Program)	CPU is forced into the RUN mode if no errors are encountered. No changes are allowed by the attached programming/monitoring device.
TERM (Terminal)	RUN, PROGRAM and the TEST modes are available. Mode and program changes are allowed by the programming/monitoring device.
STOP (Stop Program)	CPU is forced into the STOP mode. No changes are allowed by the programming/monitoring device.

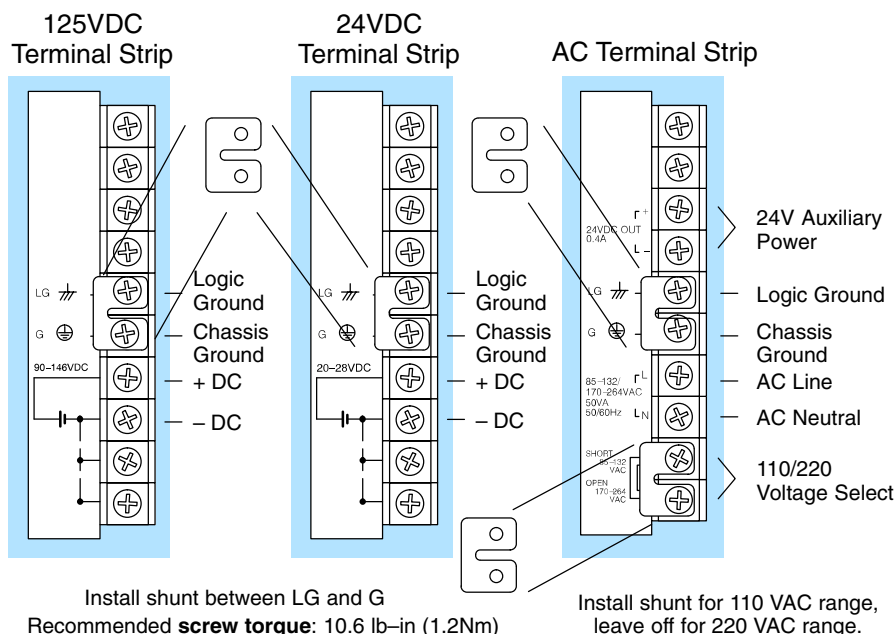

There are two ways to change the CPU mode.

1. Use the CPU key switch to select the operating mode.
2. Place the CPU key switch in the TERM position and use a programming device to change operating modes. In this position, you can change between Run and Program modes.

Status Indicators

The status indicator LEDs on the CPU front panels have specific functions which can help in programming and troubleshooting.

Indicator	Status	Meaning
PWR	ON	Power good
	OFF	Power failure
RUN	ON	CPU is in Run Mode
	OFF	CPU is in Stop Mode
CPU	ON	CPU self diagnostics error
	OFF	CPU self diagnostics good
BATT Note: Refer to page 3-12	ON	CPU battery voltage is low
	OFF	CPU battery voltage is good or disabled
DIAG (DL450)	ON	CPU self diagnostics or local bus error
	OFF	CPU self diagnostics and local bus good
I/O	ON	I/O self diagnostics error
	OFF	I/O self diagnostics good
COM (DL430/DL440)	ON	Communications error has occurred
	OFF	Communications OK
TXD (DL450)	ON	Data is being transmitted by the CPU
	OFF	No data is being transmitted by the CPU
RXD (DL450)	ON	Data is being received by the CPU
	OFF	No data is being received by the CPU

Setting the CPU DIP Switches

Locate the bank of four configuration switches located on the back of DL430 and DL440 CPUs as shown in the figure below. These switches affect battery low detection, station address override and baud rate of port 1 (25 pin D connector). Use Aux Functions on the DL450 for these selections, via a programming device.

Switch 1

- ON = Battery low indicator disabled
- OFF = Battery low indicator enabled

Switch 2

- ON = Station address override is enabled (address 1)
- OFF = Station address is set by AUX function with programming device

NOTE: Setting Switch 2 on forces the station address to 1. It does not change the address set by the programming device. When Switch 2 is turned off again the address will revert back to the address stored in memory via the AUX function.

Port 1 Baud Rate	Switch 3	Switch 4
300	Off	Off
1200	Off	On
9600	On	Off
19200	On	On

NOTE: Parity, Mode and Station address for port 1 is selected by AUX functions using a programming device.

Communication Ports

Port 0 Specifications

430 440 450

DL405 CPUs provides up to four communication ports. The DL430/DL440 CPUs have two ports, while the DL450 CPU has a total of four ports.

The first port (all CPUs) is located on the 15 pin D-shell connector. It is for general programming such as **DirectSOFT32**, or operator interface connections. The D4-HPP handheld programmer can only be used on this port on the CPU. The operating parameters for Port 0 are permanently set to the values shown.

- 15 Pin female D type connector
- Protocol: K sequence
- RS232C, non-isolated, distance within 15 m (approx. 50 feet)
- 9600 baud, 8 data bits, 1 start, 1 stop bit, odd parity
- Asynchronous, Half duplex, DTE

Port 0 Pin Descriptions (All CPUs)

1	YOP	Sense connection between HPP and CPU
2	TXD	Transmit Data (RS232C)
3	RXD	Receive Data (RS232C)
4	ONLINE	Request Communication (TTL)
5	ABNO	CPU Error (TTL)
6	PRDY	CPU ready to communicate (TTL)
7	CTS	Clear to Send (RS232C)
8	YOM	Sense connection between HPP and CPU
9	—	Not Used
10	LCBL	Sense cable connection (TTL)
11	5V2	5 VDC for HPP logic
12	5V2	5 VDC for LCD backlight
13	0V	Logic ground
14	0V	Logic ground
15	0V	Logic ground

Port 1 Specifications

430 440 450

Port 1 (all CPUs) is located on the 25-pin connector, and is called the “secondary comm port” for the DL430/DL440 CPUs. The secondary comm port address is stored in the memory cartridge along with the I/O configuration. It is for general programming such as **DirectSOFT32**, operator interfaces, and networking, but it cannot connect to the handheld programmer. Port 1 provides additional features such as programmable baud rate, parity, ASCII/Hex mode and network address. Its RS422 signals support multidrop networking and programming applications.

The baud rate and station address override is selected by dip switches on the rear of the DL430/DL440 CPUs. The DL450 uses Aux functions to set the same parameters (it has no DIP switches). RS232C or RS422 is selected by cabling to the proper signal pin sets on the connector. Parity, ASCII/Hex mode and station address are selected by AUX (auxiliary) functions with a programming device.

- 25 Pin female D type connector
- Protocols: K-sequence, **DirectNet**. The DL450 additionally supports Non-Sequence and MODBUS protocols. (Note: The DL430 cannot support K-sequence on ports 0 and 1 simultaneously. Use **DirectNet** on port 1 if port 0 is used for communications).
- RS232C / RS422, Selectable address 1–90 (use Aux function)
- 300/ 600/ 1200 / 2400 / 4800 / 9600 / 19200 / (38400 DL450 only) baud
- Hex / ASCII modes (use Aux function to configure)
- 8 data bits, 1 start, 1 stop bit, Odd, Even or No parity
- Asynchronous, Half duplex (use Aux function to configure), DTE

**Port 1 Pin Descriptions (All CPUs)**

1	–	Not used
2	TXD	Transmit Data (RS232C)
3	RXD	Receive Data (RS232C)
4	RTS	Request to Send (RS232C)
5	CTS	Clear to Send (RS232C)
6	–	Not used
7	SG	Signal ground (RS232C/RS422)
8	–	(port 3 on DL450)
9	RXD+	Receive Data + (RS422)
10	RXD–	Receive Data – (RS422)
11	CTS+	Clear to Send + (RS422)
12	–	(port 3 on DL450)
13	–	(port 3 on DL450)
14	TXD+	Transmit Data + (RS422)
15	–	Not used
16	TXD–	Transmit Data – (RS422)
17	–	Not used
18	RTS–	Request to Send – (RS422)
19	RTS+	Request to Send + (RS422)
20	–	Not used
21	–	Not used
22	–	Not used
23	CTS–	Clear to Send – (RS422)
24	–	(port 3 on DL450)
25	–	(port 3 on DL450)

Port 2 Specifications

☒ 430
 ☒ 440
 ☒ 450

The operating parameters for Port 2 on the DL450 CPU are configurable using Aux functions on a programming device.

- 6 Pin female modular (RJ12 phone jack) type connector
- Protocols: **DirectNet** (slave only), K sequence, Non-procedure
- RS232C, 300 / 600 / 1200 / 2400 / 4800 / 9600 / 19200 / 38400 baud
- 8 data bits, 1 start, 1 stop bit; odd, even, or no parity
- Nodes – from 1 to 90

**Port 2 Pin Descriptions (DL450)**

1	0V	Power (–) connection (GND)
2	5V	Power (+) connection
3	RXD	Receive Data (RS232C)
4	TXD	Transmit Data (RS232C)
5	5V	Power (+) connection
6	0V	Power (–) connection (GND)

NOTE: The 5V pins are rated at 200mA maximum, primarily for use with some operator interfaces.

Port 3 Specifications

☐ 430
 ☐ 440
 ☒ 450

The operating parameters for Port 3 on the DL450 CPU are configurable using Aux functions on a programming device.

- 25 Pin female D type connector
- Protocols: DirectNet, K-sequence, Remote I/O, MODBUS master or slave
- RS422, non-isolated, distance within 1000 ft (3280 ft.)
- 300 / 600 / 1200 / 2400 / 4800 / 9600 / 19200 / 38400 baud (DirectNet, K-sequence, MODBUS protocols), 19200 / 38400 (Remote I/O protocol)
- 8 data bits, 1 start, 1 stop bit, odd/none/even parity
- Hex / ASCII modes (use Aux function to configure)
- Selectable address 1–90 (use Aux function to configure)

Port 3 Pin Descriptions (DL450)

1	–	Not used
2		(port 1)
3		(port 1)
4		(port 1)
5		(port 1)
6	–	Not used
7	SG	Signal ground
8		Not used
9		(port 1)
10		(port 1)
11		(port 1)
12	TXD+	Transmit Data (+), (RS422)
13	TXD–	Transmit Data (–), (RS422)
14		(port 1)
15	–	Not used
16		(port 1)
17	–	Not used
18		(port 1)
19		(port 1)
20	–	Not used
21	–	Not used
22	–	Not used
23		(port 1)
24	RXD+	Receive Data (+), (RS422)
25	RXD–	Receive Data (–), (RS422)

A drawing summarizing the pin locations and functions of ports 1 and 3 on the 25-pin connector is to the right. The two logical ports share two ground pins, but have separate communications data pins. When using both logical ports, you will probably have to make a custom connector which divides the signals in two for two separate cables.

Two Logical Ports on the 25 Pin Connector

Using Battery Backup

The DL405 CPUs have a lithium battery to maintain system RAM retentive memory when the system is without external power. Typical CPU battery life is five years, which includes PLC runtime and normal shutdown periods. However, consider installing a fresh battery if your battery has not been changed recently and the system will be shutdown for a period of more than ten days.

Battery indicators will flash on and off when a battery needs changing.

- Flashing at 0.5 Hz means the CPU battery needs changing.
- Flashing at 0.25 Hz means the RAM cartridge battery needs changing.

NOTE: Be sure to back up your V-memory and system parameters before replacing your CPU battery. Just save the V-memory and system parameters to either a Memory Cartridge, cassette tape, or to a personal computer (use **DirectSOFT32**).

To prevent memory loss the CPU battery can be changed while the system is powered up. If the CPU has been powered off you should power-up the CPU for at least 5 seconds prior to changing the battery. This ensures the capacitor used to maintain the proper voltage levels necessary to retain memory is fully charged.

To remove the CPU battery:

1. Pull the battery out from the battery retaining clip.
2. Lift the clip on the two wire battery connector.
3. Slide the battery connector apart.

WARNING: Do not attempt to recharge the battery or dispose of it by fire. The battery may explode or release hazardous materials.

To install the CPU battery:

1. Join the (keyed) battery connector so that the red wires match.
2. Push gently till the connector snaps closed
3. Slide the battery all the way into the retaining clip (flush with the opening).
4. Note the date the battery was changed.

Selecting the Program Storage Media

The DL430 CPU provides built-in EEPROM storage as a standard feature, so it cannot use other types of program storage. The DL440 CPU requires a removable memory cartridge for operation. The DL450 provides built-in FLASH memory as a standard feature. It will still accept a memory cartridge for program storage. The following paragraphs will help you choose the correct memory storage for your CPU type and application.

NOTE: The source memory (either cartridge or internal) must be specified by using either **DirectSOFT32** or the handheld programmer (D4-HPP).

Volatile and Non-volatile Memory

The two types of memory storage available are volatile and non-volatile. Volatile memory retains your data only as long as proper voltage is maintained to the storage media. Non-volatile memory does not require power to retain data. The DL405 CPUs maintain the proper voltage either through the power supply or the use of a memory backup battery.

Memory Storage Types

Memory cartridges are applicable to only the DL440 and DL450 CPUs. One cartridge is required on the DL440, but is optional on the DL450. The removable memory cartridge is available as either CMOS RAM, UVPROM or EEPROM. The RAM and EEPROM types offer a write protect jumper selection internal to the cartridge. When the cartridge is opened the jumper may be moved to the protect position to prevent accidental erasure or alterations to the program.

- CMOS RAM (Complementary Metal Oxide Semiconductor / Random Access Memory) requires a battery for memory retention, which is located inside the cartridge. The memory can be modified or changed easily with a handheld programmer or PC programming software. Battery life is typically 3 years. Refer to Chapter 9, Maintenance and Troubleshooting for battery replacement.
- UVPROM (Ultraviolet Programmable Read Only Memory) does not require a battery for memory retention, so it is classified as “non-volatile”. However, erasure (clearing memory) requires exposing the memory ICs to an ultraviolet light source. The CPU can reprogram the UVPROM cartridge after erasure, but this requires a handheld programmer.

NOTE: When you purchase the UVPROM memory cartridge it is recommended you have either a RAM or an EEPROM memory cartridge for program development. Once development is completed you should then use the handheld programmer (D4-HPP) to copy your application program to the UVPROM. We recommend the UVPROM memory cartridge option for applications which are mass produced and do not require frequent alterations.

- EEPROM (Electrically Erasable Programmable Read Only Memory) does not require a battery for memory retention, so it is classified as “non-volatile”. Both erasure and programming are accomplished electrically, eliminating ultraviolet light source requirement. So, the EEPROM memory cartridge can be electrically reprogrammed (if not write protected) without being removed from the CPU. This is the memory type built into the DL430 CPU.

Memory Cartridge The diagram below displays a Memory Cartridge for the DL440 or DL450. It shows how the memory cartridge fits in the CPU and in the handheld programmer. It also shows how to open the memory cartridge for selecting write protect (for CMOS RAM) or for erasing the UVPROM. Details about connecting the handheld programmer to the CPU is covered in DL405 Handheld Programmer Manual.

WARNING: Do not insert or remove a CPU memory cartridge while the power is connected. Your program or password may be corrupted if this occurs. A corrupted program can cause unpredictable operation which may result in a risk of injury to personnel or damage to equipment. If the password becomes corrupted, you cannot access the CPU.

Memory Cartridge Capacity Table

	D4-RAM-1	D4-RAM-2	D4-UV-1	D4-UV-2	D4-EE-2
Program Storage Capacity	7.5K	15.5K	7.5 K	15.5K	15.5K
Cartridge Battery Type	Lithium	Lithium	None	None	None
Writing Cycle Life	N/A	N/A	1000	1000	>10,000
Write Inhibit	Internal jumper	Internal jumper	No	No	Internal jumper
Memory Clear Method	Electrical	Electrical	Ultraviolet light	Ultraviolet light	Electrical

CPU Setup

Setting the Clock and Calendar

The DL440 and DL450 CPUs also have a Clock / Calendar that can be used for many purposes. If you need to use this feature there are also AUX functions available that allow you set the date and time. For example, you would use AUX 52, Display/Change Calendar to set the time and date with the Handheld Programmer. With **DirectSOFT32** you would use the PLC Setup menu options.

There are also two instructions that allow you to change or modify the time and date from within the application program. Chapter 5 provides information on the DATE and TIME instructions that are used to establish the clock and calendar information.

The CPU uses the following format to display the date and time.

Handheld Programmer Display

- Date — Year, Month, Date, Day of week (0 – 6, Sunday thru Saturday)
- Time — 24 hour format, Hours, Minutes, Seconds

94/01/02 23:08:17

You can use the AUX function to change any component of the date or time. However, the CPU will not automatically correct any discrepancy between the date and the day of the week. For example, if you change the date to the 15th of the month and the 15th is on a Thursday, you will also have to change the day of the week (unless the CPU already shows the date as Thursday).

Variable / Fixed Scan Time Feature

The DL450 CPU offers three type of scan time configurations:

- **Variable** – this is the standard scan time setting, in which the PLC scan is running as fast as the ladder program execution allows.
- **Fixed** – the scan time may be set to be constant, from 10 mS to 9999 mS. The operating system inserts a delay after each ladder scan to accomplish the requested fixed scan.
- **Limit** – the PLC operates with a variable scan, but generates a watchdog timeout error if the scan time exceeds the specified amount. You can use this to trap program execution errors, for example.

To select the desired DL450 scan time option, use **DirectSOFT32** and go online with the DL450. Then select the PLC Menu, then Diagnostics, then Scantime, then Setup. The three choices of Variable, Fixed, or Limit then appear.

Password Protection

The DL405 CPUs have a password protection feature which prevents unauthorized access to CPU programs or data. Use AUX 81, 82, and 83 to either modify the password, and unlock or lock the CPU respectively. The password must be an eight-character numeric (0–9) code. Once you've entered a password, you can remove it by entering all zeros (00000000). (This is the default from the factory.)

Multilevel Password (DL440/450 only) – The DL440 and DL450 feature an intermediate level of protection that you can choose by making the first character of the password the character "A". The remaining 7 characters must be numeric (0–9). The intermediate password protection differs from the standard password in that it does allow an operator interface device to access and change V-memory data such as presets. It still does not allow a ladder program edit, however.

For more information on passwords, see the appendix on auxiliary functions.

Auxiliary Functions Many CPU setup tasks involve the use of Auxiliary (AUX) Functions. The AUX Functions perform many different operations, ranging from simple operating mode changes to copying programs to memory cartridges. They are divided into categories that affect different system parameters. See Appendix A for detailed descriptions of the AUX functions.

You can access the AUX Functions with the DL405 Handheld Programmer, or with **DirectSOFT32's** pull-down menus. Manuals for those products provide step-by-step instructions. Some AUX Functions are designed specifically for Handheld Programmer setup, so they are not supported by **DirectSOFT32**. The following table lists the Auxiliary functions for the different CPUs and the Handheld Programmer.

AUX Function and Description		430	440	450	HPP
AUX 1* — Operating Mode					
11	Go to Run Mode	✓	✓	✓	—
12	Go to Test Mode	✓	✓	✓	—

Clearing an Existing Program

Before entering a new program, it's a good idea to always clear ladder memory. AUX Function 24 clears the complete user program.

You can also use other AUX functions to clear other memory areas.

- AUX 23 — Clear Ladder Range
- AUX 31 — Clear V Memory
- AUX 32 — Clear V Range

Initializing System Memory

The DL405 CPUs maintain system parameters in a memory area often referred to as the “scratchpad”. In some cases, you may make changes to the system setup that will be stored in system memory. For example, if you specify a range of Control Relays (CRs) as retentive, these changes are stored.

AUX 54 resets the system memory to the default values.

WARNING: You may never have to use this feature unless you want to clear any setup information that is stored in system memory. Usually, you'll only need to initialize the system memory if you are changing programs and the old program required a special system setup. You can usually change from program to program without ever initializing system memory. Remember, this AUX function will reset *all* system memory. If you have set special parameters such as retentive ranges, you will need to re-enter the data.

Setting the CPU Network Address

Since the DL405 CPUs have built-in **DirectNET** ports, you can use the Handheld Programmer to set the network address for the port and the port communication parameters. The default settings are:

- Station address 1
- Hex mode
- Odd parity

The **DirectNET** Manual provides additional information about choosing the communication settings for network operation. If you're using the bottom port for programming, you can just use the default settings. For the extra two ports on the DL450, see Chapter 4, System Design and Configuration.

Use AUX 56 to set the network address and communication parameters for the secondary port(s).

Setting Retentive Memory Ranges

The DL405 CPUs provide certain ranges of retentive memory by default. The default ranges are suitable for many applications, but you can change them if your application requires additional retentive ranges or no retentive ranges at all. The default settings are:

Memory Area	DL430		DL440		DL450	
	Default Range	Avail. Range	Default Range	Avail. Range	Default Range	Avail. Range
Control Relays	C600 – C737	C0 – C737	C600 – C737	C0 – C1777	C1000 – C3777	C0 – C3777
V Memory	V2000 – V7377	V0 – V7377	V2000 – V7777	V0 – V17777	V1400 – V37777	V0 – V37777
Timers	None by default	T0 – T177	None by default	T0 – T377	None by default	T0 – T377
Counters	CT0 – CT177	CT0 – CT177	CT0 – CT177	CT0 – CT177	CT0 – CT377	CT0 – CT377
Stages	None by default	S0 – S577	None by default	S0 – S1777	None by default	S0 – S1777

Use AUX 57 to set the retentive ranges.

CPU Operation

Achieving the proper control for your equipment or process requires a good understanding of how DL405 CPUs control all aspects of system operation. The flow chart below shows the main tasks of the CPU operating system. In this section, we will investigate four aspects of CPU operation:

- **CPU Operating System** — the CPU manages all aspects of system control.
- **CPU Operating Modes** — The three primary modes of operation are Program Mode, Run Mode, and Test Mode.
- **CPU Timing** — The two important areas we discuss are the I/O response time and the CPU scan time.
- **CPU Memory Map** — The CPU's memory map shows the CPU addresses of various system resources, such as timers, counters, inputs, and outputs.

CPU Operating System

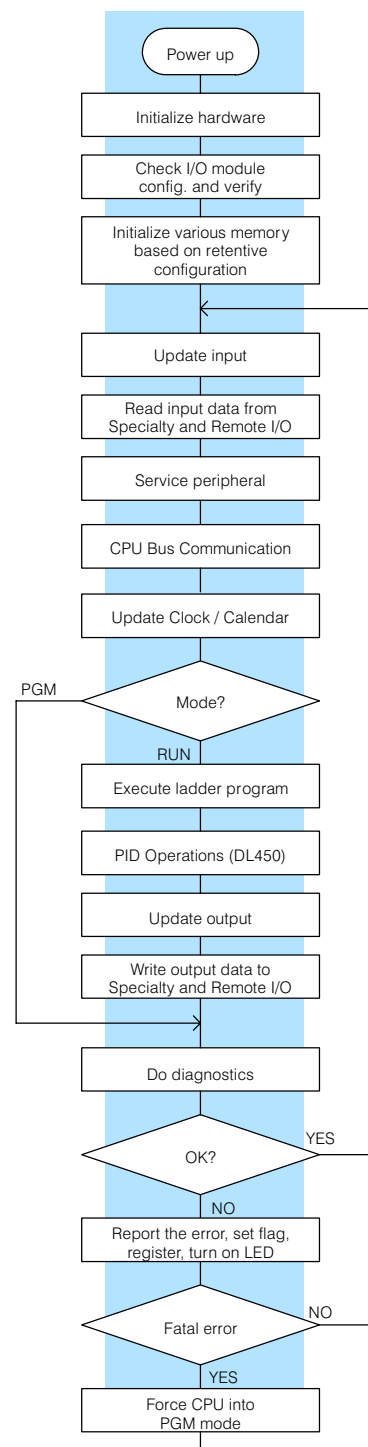

At powerup, the CPU initializes the internal electronic hardware. Memory initialization starts with examining the retentive memory settings. In general, the contents of retentive memory is preserved, and non-retentive memory is initialized to zero (unless otherwise specified).

After the one-time powerup tasks, the CPU begins the cyclical scan activity. The flowchart to the right shows how the tasks differ, based on the CPU mode and the existence of any errors. The “*scan time*” is defined as the average time around the task loop. Note that the CPU is always reading the inputs, even during program mode. This allows programming tools to monitor input status at any time.

The outputs are only updated in Run mode. In program mode, they are in the off state.

In Run Mode, the CPU executes the user ladder program. Immediately afterwards, any PID loops which are configured are executed (DL450 only). Then the CPU writes the output results of these two tasks to the appropriate output points.

Error detection has two levels. Non-fatal errors are reported, but the CPU remains in its current mode. If a fatal error occurs, the CPU is forced into program mode and the outputs go off.

Program Mode Operation

In Program Mode the CPU does not execute the application program or update the output modules. The primary use for Program Mode is to enter or change an application program. You also use the program mode to set up CPU parameters, such as the network address, retentive memory areas, etc.

Download Program

You can use the key switch on the CPU to select Program Mode operation. Or, with the keyswitch in TERM position, you can use a programming device such as the Handheld Programmer to place the CPU in Program Mode.

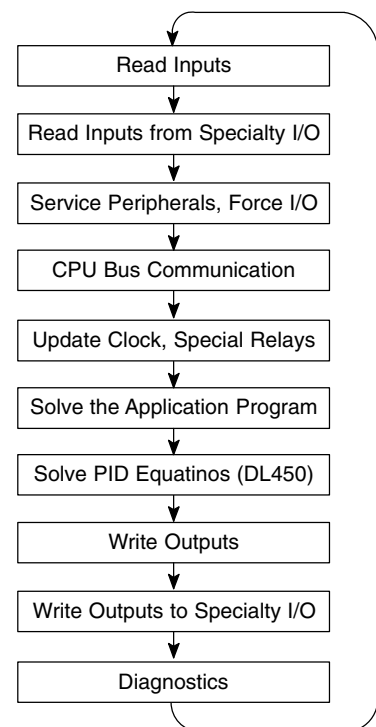

Run Mode Operation

In Run Mode, the CPU executes the application program, does PID calculations for configured PID loops (DL450) only, and updates the I/O system. You can perform many operations during Run Mode. Some of these include:

- Monitor and change I/O point status
- Update timer/counter preset values
- Update Variable memory locations

Run Mode operation can be divided into several key areas. It is very important you understand how each of these areas of execution can affect the results of your application program solutions.

You can use the key switch to select Run Mode operation. Or, with the keyswitch in TERM position, you can use a programming device, such as the Handheld Programmer to place the CPU in Run Mode.

With the DL440 or DL450, you can also edit the program during Run Mode. The Run Mode Edits are not “bumpless.” Instead, the CPU maintains the outputs in their last state while it accepts the new program information. If an error is found in the new program, then the CPU will turn all the outputs off and enter the Program Mode.

WARNING: Only authorized personnel fully familiar with all aspects of the application should make changes to the program. Changes during Run Mode become effective immediately. Make sure you thoroughly consider the impact of any changes to minimize the risk of personal injury or damage to equipment.

Read Inputs

The CPU reads the status of all inputs, then stores it in the image register. Input image register locations are designated with an X followed by a memory location. Image register data is used by the CPU when it solves the application program.

Of course, an input may change *after* the CPU has just read the inputs. Generally, the CPU scan time is measured in milliseconds. If you have an application that cannot wait until the next I/O update, you can use Immediate Instructions. These do not use the status of the input image register to solve the application program. The Immediate instructions immediately read the input status directly from I/O modules. However, this lengthens the program scan since the CPU has to read the I/O point status again. A complete list of the Immediate instructions is included in Chapter 5.

Read Inputs from Specialty and Remote I/O

After the CPU reads the inputs from the input modules, it reads any input point data from any Specialty modules that are installed, such as High Speed Counter modules, etc. This is also the portion of the scan that reads the input status from Remote I/O racks. The GX data type is used for both remote inputs and outputs. (The DL405 Remote and Slice I/O Manual provides additional information on how to set up the remote I/O link.)

NOTE: It may appear the Remote I/O point status is updated every scan. This is not quite true. The CPU will receive information from the Remote I/O Master module every scan, but the Remote Master may not have received an update from all the Remote slaves. Remember, the Remote I/O link is managed by the Remote Master, not the CPU.

Service Peripherals and Force I/O

After the CPU reads the inputs from the input modules, it reads any attached peripheral devices. This is primarily a communications service for any attached devices. For example, it would read a programming device to see if any input, output, or other memory type status needs to be modified.

Forced I/O— temporarily changes the status of a discrete bit. For example, you may want to force an input on, even though it is really off. This allows you to change the point status that was stored in the image register. This value will be valid until the image register location is written to *during the next scan*. This is primarily useful during testing situations when you just need to force a bit on to trigger another event.

Forced Inputs — The CPU reads the status of X inputs during the Read Inputs portion of the scan. When the CPU services the programming device, it logs any request to force an X input on. If the input is used in the application program, the ladder X contact is considered closed (on). Since an X input is a real-world input point, the CPU will change the status when it reads the inputs on the next scan.

Forced Outputs— Outputs which are not used in the program can be forced on and off for troubleshooting and maintenance purposes. You can temporarily allow the forcing of any output by inserting an END coil instruction at the beginning of the ladder program. Then you can use **DirectSOFT32** or a HPP to force outputs on and off.

The DL405 CPUs only retain the forced value for one scan, if the I/O point corresponds to an actual point on a module in the system. However, if the point address is greater than any actual I/O point address in the system or it is not used in the ladder program, then the point will maintain the forced status.

WARNING: Only authorized personnel fully familiar with all aspects of the application should make changes to the program. Make sure you thoroughly consider the impact of any changes to minimize the risk of personal injury or damage to equipment.

Update Special Relays and Special Registers

There are certain V-memory locations that contain register information. This portion of the execution cycle makes sure these locations get updated on every scan. Also, there are several different Special Relays, such as diagnostic relays, etc., that are also updated during this segment.

CPU Bus Communication

Many of the Specialty Modules, such as the Data Communications Module and the FACTS CoProcessor modules, can transfer data to and from the CPU over the CPU bus on the backplane. This data is more than just standard I/O point status. This type of communications can only occur on the CPU (local) base. There is a portion of the execution cycle used to communicate with these modules. The CPU performs both read and write requests during this segment.

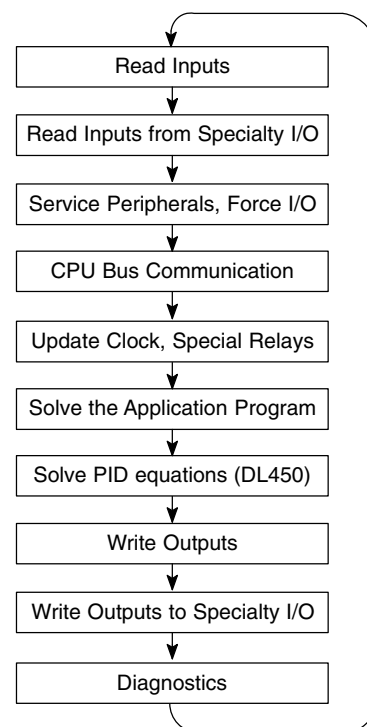

Update Clock, Special Relays, and Special Registers

The DL440 and DL450 CPUs have an internal real-time clock and calendar timer which is accessible to the application program. Special V-memory locations hold this information. This portion of the execution cycle makes sure these locations get updated on every scan. Also, there are several different Special Relays, such as diagnostic relays, etc., that are also updated during this segment.

Solve Application Program

The CPU evaluates each instruction in the application program during this segment of the scan cycle. The instructions define the relationship between input conditions and the system outputs.

The CPU begins with the first rung of the ladder program, evaluating it from left to right and from top to bottom. It continues, rung by rung, until it encounters the END coil instruction. At that point, a new image for the outputs is complete.

The internal control relays (C), the stages (S), the global relays (GX), and the variable memory (V) are also updated in this segment.

You may recall the CPU may have obtained and stored forcing information when it serviced the peripheral devices. If any I/O points or memory data have been forced, the output image register also contains this information.

NOTE: If an output point was used in the application program, the results of the program solution will overwrite any forcing information that was stored. For example, if Y0 was forced on by the programming device, and a rung containing Y0 was evaluated such that Y0 should be turned off, then the output image register will show that Y0 should be off. Of course, you can force output points that are not used in the application program. In this case, the point remains forced because there is no solution that results from the application program execution.

Solve PID Loop Equations

430 440 450

The DL450 CPU can process up to 16 PID loops. The loop calculations are run as a separate task from the ladder program execution, immediately following it. Only loops which have been configured are calculated, and then only according to a built-in loop scheduler. The sample time (calculation interval) of each loop is programmable. Please refer to Chapter 8, PID Loop Operation, for more on the effects of PID loop calculation on the overall CPU scan time.

Write Outputs

Once the application program has solved the instruction logic and constructed the output image register, the CPU writes the contents of the output image register to the corresponding output points located in the local CPU base or the local expansion bases. Remember, the CPU also made sure any forcing operation changes were stored in the output image register, so the forced points get updated with the status specified earlier.

Write Outputs to Specialty and Remote I/O

After the CPU updates the outputs in the local and expansion bases, it sends the output point information that is required by any Specialty modules which are installed. For example, this is the portion of the scan that writes the output status from the image register to the Remote I/O racks.

NOTE: It may appear the Remote I/O point status is updated every scan. This is not quite true. The CPU will send the information to the Remote I/O Master module every scan, but the Remote Master will update the actual remote modules during the next communication sequence between the master and slave modules. Remember, the Remote I/O link communication is managed by the Remote Master, not the CPU.

Diagnostics

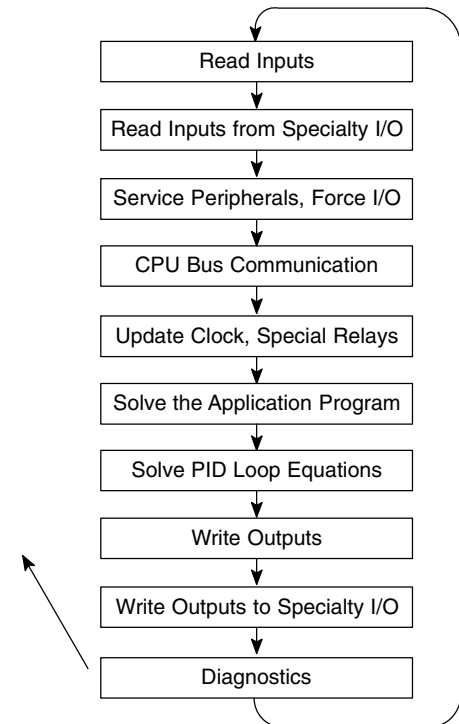

During this part of the scan, the CPU performs all system diagnostics and other tasks, such as:

- calculating the scan time
- updating special relays
- resetting the watchdog timer

DL405 CPUs automatically detect and report many different error conditions. Appendix B contains a listing of the various error codes available with the DL405 system.

One of the more important diagnostic tasks is the scan time calculation and watchdog timer control. DL405 CPUs have a “watchdog” timer that stores the maximum time allowed for the CPU to complete the solve application segment of the scan cycle. The default value set from the factory is 200 mS. If this time is exceeded the CPU will enter the Program Mode, turn off all outputs, and report the error. For example, the Handheld Programmer displays “E003 S/W TIMEOUT” when the scan overrun occurs.

You can use AUX 53 to view the minimum, maximum, and current scan time. Use AUX 55 to increase or decrease the watchdog timer value. There is also an RSTWT instruction that can be used in the application program to reset the watch dog timer during the CPU scan.

I/O Response Time

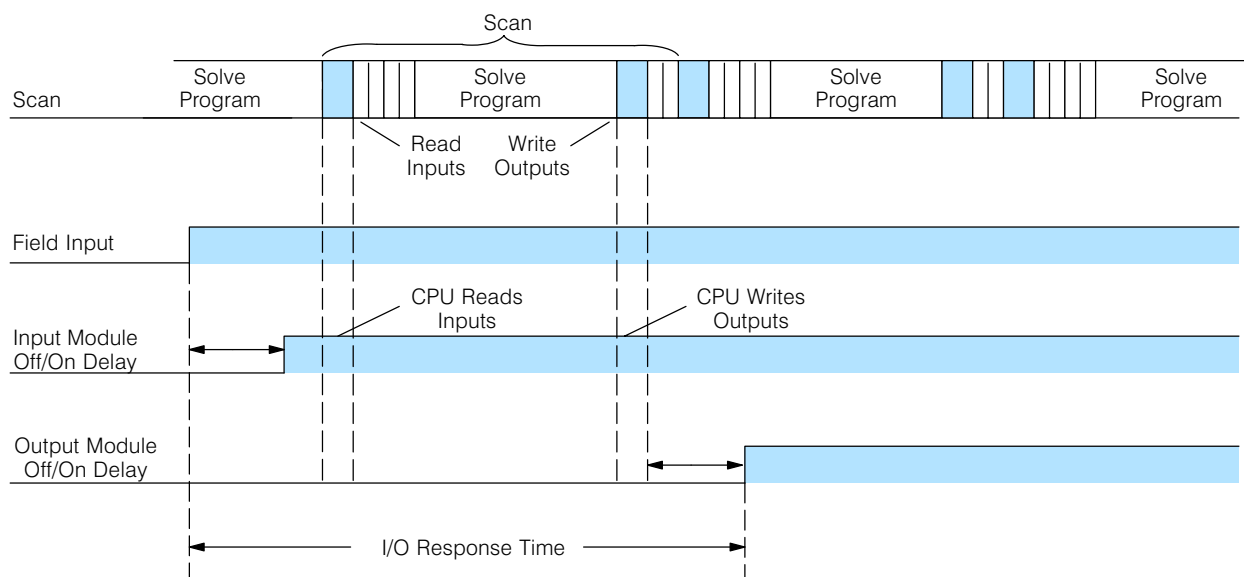

Is Timing Important for Your Application?

I/O response time is the amount of time required for the control system to sense a change in an input point and update a corresponding output point. In the majority of applications, the CPU performs this task practically instantaneously. However, some applications do require extremely fast update times. There are four things that can affect the I/O response time:

- The point in the scan period when the field input changes states
- Input module Off to On delay time
- CPU scan time
- Output module Off to On delay time

Normal Minimum I/O Response

The I/O response time is shortest when the module senses the input change just before the Read Inputs portion of the execution cycle. In this case the input status is read, the application program is solved, and the output point gets updated. The following diagram shows an example of the timing for this situation.

In this case, you can calculate the response time by simply adding the following items.

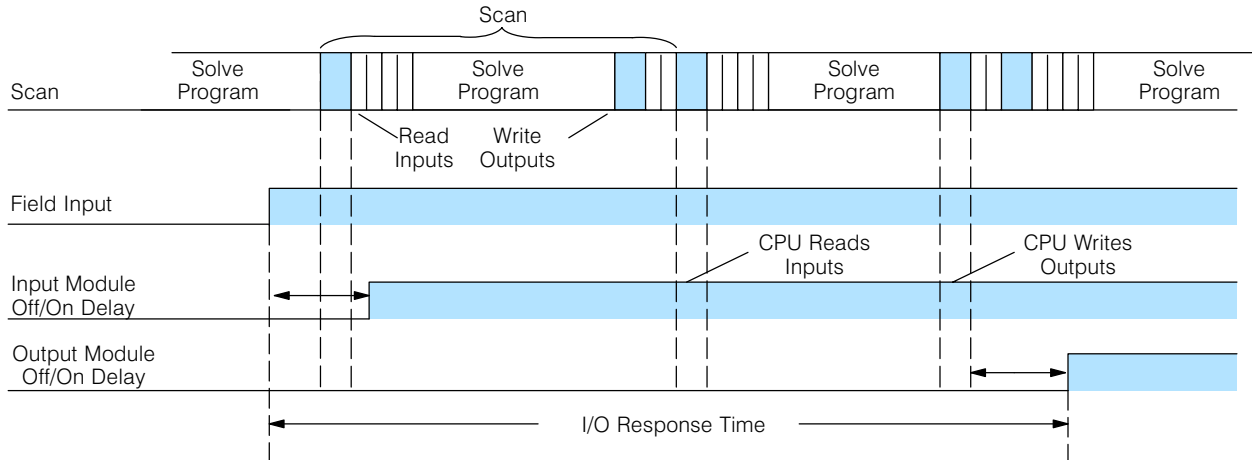

$$\text{Input Delay} + \text{Scan Time} + \text{Output Delay} = \text{Response Time}$$

Normal Maximum I/O Response

The I/O response time is longest when the module senses the input change just after the Read Inputs portion of the execution cycle. In this case the new input status does not get read until the following scan. The following diagram shows an example of the timing for this situation.

In this case, you can calculate the response time by simply adding the following items.

$$\text{Input Delay} + (2 \times \text{Scan Time}) + \text{Output Delay} = \text{Response Time}$$

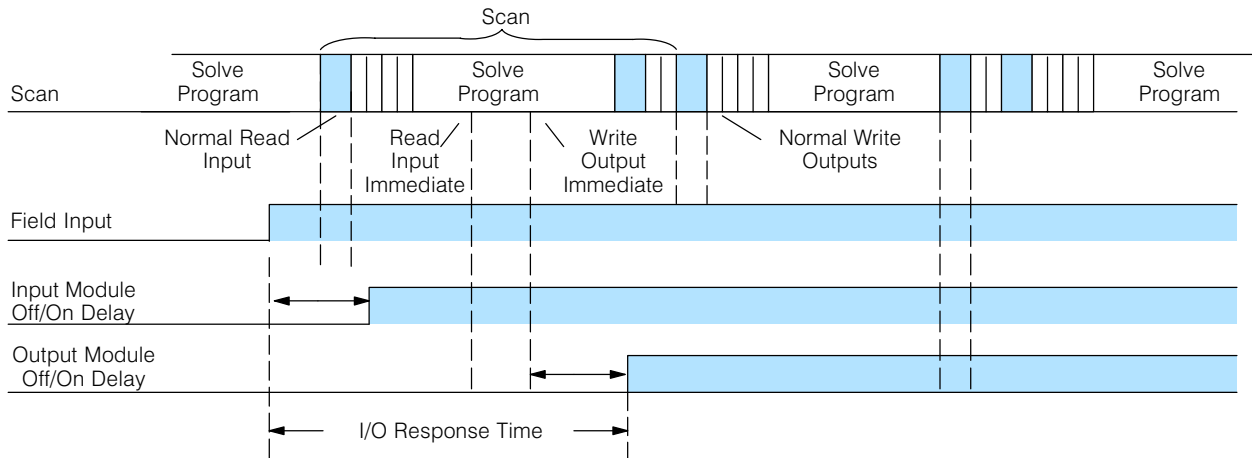

Improving Response Time

There are a few things you can do to help improve throughput.

- Choose instructions with faster execution times
- Use immediate I/O instructions (which update the I/O points during the ladder program execution segment)
- Choose modules that have faster response times

Immediate I/O instructions are probably the most useful technique. The following example shows immediate input and output instructions, and their effect.

In this case, you can calculate the response time by simply adding the following items.

$$\text{Input Delay} + \text{Instruction Execution Time} + \text{Output Delay} = \text{Response Time}$$

The instruction execution time is calculated by adding the time for the immediate input instruction, the immediate output instruction, and all instructions in between.

NOTE: When the immediate instruction reads the current status from a module, it uses the results to solve that one instruction without updating the image register. Therefore, any regular instructions that follow will still use image register values. Any immediate instructions that follow will access the module again to update the status.

CPU Scan Time Considerations

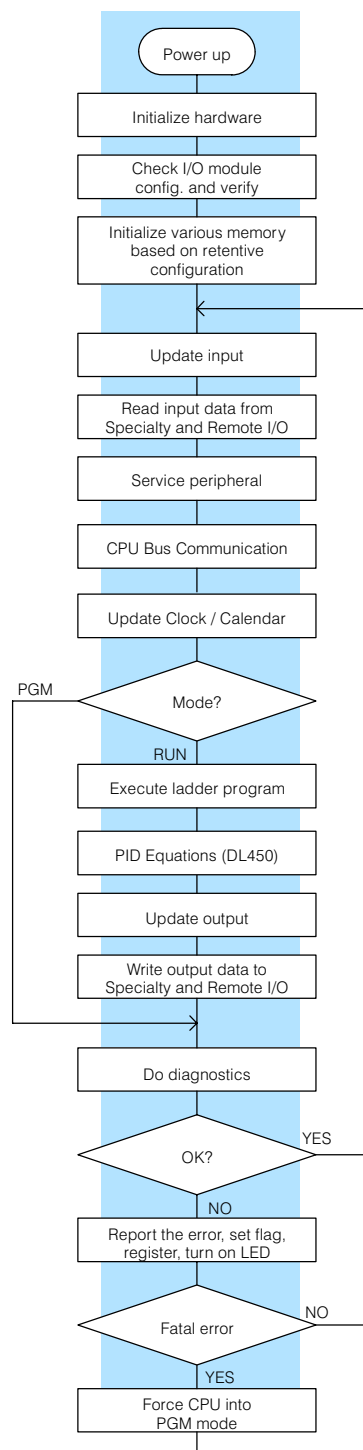

The scan time covers all the cyclical tasks that are performed by the operating system. You can use **DirectSOFT32** or the Handheld Programmer to display the minimum, maximum, and current scan times that have occurred since the previous Program Mode to Run Mode transition. This information can be very important when evaluating the performance of a system.

As we've shown previously there are several segments that make up the scan cycle. Each of these segments requires a certain amount of time to complete. Of all the segments, the only one you really have the most control over is the amount of time it takes to execute the application program. This is because different instructions take different amounts of time to execute. So, if you think you need a faster scan, then you can try to choose faster instructions.

Your choice of I/O modules and system configuration, such as expansion or remote I/O, can also affect the scan time. However, these things are usually dictated by the application.

For example, if you have a need to count pulses at high rates of speed, then you'll probably have to use a High-Speed Counter module. Also, if you have I/O points that need to be located several hundred feet from the CPU, then you need remote I/O because it's much faster and cheaper to install a single remote I/O cable than it is to run all those signal wires for each individual I/O point.

The following paragraphs provide some general information on how much time some of the segments can require.

Initialization Process

The CPU performs an initialization task once the system power is on. The required time depends on system loading, such as the number of I/O modules installed, type of memory cartridge being used etc. The initialization task is performed once at power-up, so it does not affect the scan time for the application program.

Initialization	DL430	DL440	DL450
Minimum Time	1.2 Seconds	1.0 Seconds	1.9 Seconds
Maximum Time	3.2 Seconds	2.5 Seconds	3.3 Seconds

Reading Inputs

The time required to read the input status for the local and expansion input modules depends on which CPU you are using, the number of input points in these bases, and the number of input modules being used. The following table shows typical update times required by the CPU.

Timing Factors	DL430	DL440	DL450
Overhead	20.0 μ s	14.5 μ s	20.0 μ s
Per input module	48.0 μ s	22.6 μ s	13.0 μ s
Per input point	4.0 μ s	2.5 μ s	6.3 μ s

For example, the time required for a DL430 to read two 16-point input modules would be calculated as follows. (Where NM is the number of modules and NI is the total number of input points.)

Formula

$$\text{Time} = 20\mu\text{s} + (48\mu\text{s} \times \text{NM}) + (4\mu\text{s} \times \text{NI})$$

Example

$$\text{Time} = 20\mu\text{s} + (48\mu\text{s} \times 2) + (4\mu\text{s} \times 16)$$

$$\text{Time} = 180 \mu\text{s}$$

NOTE: This information provides the amount of time the CPU spends reading the input status from the modules. Don't confuse this with the I/O response time that was discussed earlier.

Reading Inputs from Specialty I/O

During this portion of the cycle the CPU reads any input points associated with the following.

- Remote I/O
- Specialty Modules (such as High-Speed Counter, etc.)

The time required to read any input status from these modules depends on which CPU you are using, the number of modules, and the number of input points.

Specialty Module	DL430	DL440	DL450
Overhead	32.0 μ s	20.0 μ s	20.0 μ s
Per module (with inputs)	100.0 μ s	67.0 μ s	13.0 μ s
Per input point	80.0 μ s	54.0 μ s	13.8 μ s
Remote Module	DL430	DL440	DL450
Overhead	32.0 μ s	22.0 μ s	19.0 μ s
Per module (with inputs)	150.0 μ s	100.0 μ s	62.0 μ s
Per input point	25.0 μ s	17.0 μ s	11.2 μ s

For example, the time required for a DL430 to read two 32-point input modules (located in a Remote base) and the input points associated with a single High-Speed Counter module would be calculated as follows. (Where NM is the number of modules and NI is the total number of input points.)

Remote I/O**Formula**

$$\text{Time} = 32\mu\text{s} + (150\mu\text{s} \times \text{NM}) + (25\mu\text{s} \times \text{NI})$$

Example

$$\text{Time} = 32\mu\text{s} + (150\mu\text{s} \times 2) + (25\mu\text{s} \times 32)$$

$$\text{Time} = 1832 \mu\text{s}$$

High-Speed Counter**Formula**

$$\text{Time} = 32\mu\text{s} + (100\mu\text{s} \times \text{NM}) + (80\mu\text{s} \times \text{NI})$$

Example

$$\text{Time} = 32\mu\text{s} + (100\mu\text{s} \times 1) + (80\mu\text{s} \times 16)$$

$$\text{Time} = 1412 \mu\text{s}$$

$$\text{Total Time} = 1832 \mu\text{s} + 1412 \mu\text{s} = 3244 \mu\text{s}$$

Service Peripherals Communication requests can occur at any time during the scan, but the CPU only “logs” the requests for service until the Service Peripherals portion of the scan. (The CPU does not spend any time on this if there are no peripherals connected.)

To Log Request (anytime)		DL430	DL440	DL450
Nothing Connected	Min. & Max.	0 μ s	0 μ s	0 μ s
Port 0	Send Min. / Max.	52 / 62 μ s	40 / 48 μ s	38 / 38 μ s
	Rec. Min. / Max.	60 / 78 μ s	52 / 63 μ s	45 / 45 μ s
Port 1	Send Min. / Max.	60 / 78 μ s	46 / 50 μ s	41 / 48 μ s
	Rec. Min. / Max.	68 / 86 μ s	66 / 70 μ s	47 / 59 μ s
Port 2	Send Min. / Max.	N/A	N/A	41 / 48 μ s
	Rec. Min. / Max.	N/A	N/A	47 / 59 μ s
Port 3	Send Min. / Max.	N/A	N/A	38 / 38 μ s
	Rec. Min. / Max.	N/A	N/A	45 / 45 μ s

During the Service Peripherals portion of the scan, the CPU analyzes the communications request and responds as appropriate. The amount of time required to service the peripherals depends on the content of the request.

To Service Request	DL430	DL440	DL450
Minimum	170 μ s	120 μ s	96 μ s
Run Mode Max.	18 ms	26 ms	160 ms
Program Mode Max.	3 Seconds	15 Seconds	11.2 Seconds

CPU Bus Communication

Some specialty modules can also communicate directly with the CPU via the CPU bus. During this portion of the cycle the CPU completes any CPU bus communications. The actual time required depends on the type of modules installed and the type of request being processed.

NOTE: Some specialty modules can have a considerable impact on the CPU scan time. If timing is critical in your application, consult the module documentation for any information concerning the impact on the scan time.

Update Clock / Calendar, Special Relays, Special Registers

The clock, calendar, and special relays are updated and loaded into special V-memory locations during this time. This update is performed during both Run and Program Modes.

Modes		DL430	DL440	DL450
Program Mode	Minimum	8.0 μ s fixed	35.0 μ s	12.0 μ s
	Maximum	8.0 μ s fixed	48.0 μ s	12.0 μ s
Run Mode	Minimum	20.0 μ s	60.0 μ s	22.0 μ s
	Maximum	26.0 μ s	85.0 μ s	29.0 μ s

Writing Outputs

The time required to write the output status for the local and expansion I/O modules depends on which CPU you are using, the number of output points in these bases, and the number of output modules being used. The following table shows typical update times required by the CPU.

Timing Factors	DL430	DL440	DL450
Overhead	20.0 μ s	12.6 μ s	15.0 μ s
Per output module	45.0 μ s	21.0 μ s	13.0 μ s
Per output point	4.0 μ s	2.5 μ s	14.1 μ s

For example, the time required for a DL430 to write data for two 32-point output modules would be calculated as follows (where NM is the number of modules and NO is the total number of output points).

Formula

$$\text{Time} = 20\mu\text{s} + (45\mu\text{s} \times \text{NM}) + (4\mu\text{s} \times \text{NO})$$

Example

$$\text{Time} = 20\mu\text{s} + (45\mu\text{s} \times 2) + (4\mu\text{s} \times 32)$$

$$\text{Time} = 238 \mu\text{s}$$

Writing Outputs to Specialty I/O

During this portion of the cycle the CPU writes any output points associated with the following.

- Remote I/O
- Specialty Modules (such as High-Speed Counter, etc.)

The time required to write any output image register data to these modules depends on which CPU you are using, the number of modules, and the number of output points.

Specialty Module	DL430	DL440	DL450
Overhead	32.0 μ s	20.0 μ s	18.0 μ s
Per module (with outputs)	100.0 μ s	67.0 μ s	13.0 μ s
Per output point	80.0 μ s	54.0 μ s	14.1 μ s
Remote Module	DL430	DL440	DL450
Overhead	32.0 μ s	22.0 μ s	15.0 μ s
Per module (with outputs)	150.0 μ s	100.0 μ s	54.0 μ s
Per output point	25.0 μ s	17.0 μ s	13.9 μ s

For example, the time required for a DL430 to write two 32-point output modules (located in a Remote base) and the output points associated with a single High-Speed Counter module would be calculated as follows. (Where NM is the number of modules and NO is the total number of output points.)

Remote I/O**Formula**

$$\text{Time} = 32\mu\text{s} + (150\mu\text{s} \times \text{NM}) + (25\mu\text{s} \times \text{NO})$$

Example

$$\text{Time} = 32\mu\text{s} + (150\mu\text{s} \times 2) + (25\mu\text{s} \times 32)$$

$$\text{Time} = 1832 \mu\text{s}$$

High-Speed Counter**Formula**

$$\text{Time} = 32\mu\text{s} + (100\mu\text{s} \times \text{NM}) + (80\mu\text{s} \times \text{NO})$$

Example

$$\text{Time} = 32\mu\text{s} + (100\mu\text{s} \times 1) + (80\mu\text{s} \times 4)$$

$$\text{Time} = 452 \mu\text{s}$$

Total Time

$$\text{Time} = 2284 \mu\text{s}$$

NOTE: This total time is the actual time required for the CPU to update these outputs. This does not include any additional time that is required for the CPU to actually service the particular specialty modules.

Diagnostics

The DL405 CPUs perform many types of system diagnostics. The amount of time required depends on many things, such as the number of I/O modules installed, etc. The following table shows the minimum and maximum times that can be expected.

Diagnostic Time	DL430	DL440	DL450
Minimum	680.0 μ s	540.0 μ s	282.0 μ s
Maximum	880.0 μ s	920.0 μ s	398.0 μ s

Application Program Execution

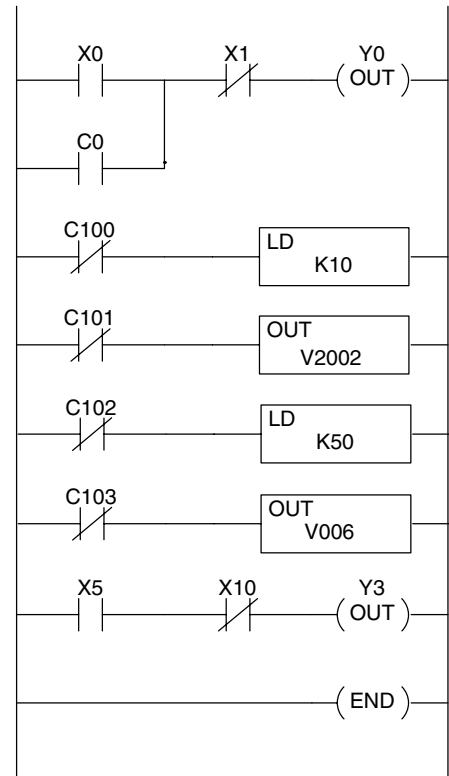

The CPU processes the program from the top (address 0) to the END instruction. The CPU executes the program left to right and top to bottom. As each rung is evaluated the appropriate image register or memory location is updated.

The time required to solve the application program depends on the type and number of instructions used, and the amount of execution overhead.

You can add the execution times for all the instructions in your program to find the total program execution time.

For example, the execution time for a DL430 running the program shown would be calculated as follows.

Instruction	Time
STR X0	4.7µs
OR C0	3.1µs
ANDN X1	3.4µs
OUT Y0	8.3µs
STRN C100	5.7µs
LD K10	112.0µs
STRN C101	8.3µs
OUT V2002	26.0µs
STRN C102	8.3µs
LD K50	112.0µs
STRN C103	8.3µs
OUT V0006	26.0µs
STR X5	4.7µs
ANDN X10	3.4µs
OUT Y3	8.3µs
END	15.5µs
TOTAL	358µs

Appendix C provides a complete list of instruction execution times for DL405 CPUs.

Program Control Instructions — the DL440 and DL450 CPUs offer additional instructions that can change the way the program executes. These instructions include FOR/NEXT loops, Subroutines, and Interrupt Routines. These instructions can interrupt the normal program flow and effect the program execution time. Chapter 5 provides detailed information on how these different types of instructions operate.

PLC Numbering Systems

If you are a new PLC user or are using AutomationDirect PLCs for the first time, please take a moment to study how our PLCs use numbers. You'll find that each PLC manufacturer has their own conventions on the use of numbers in their PLCs. We want to take just a moment to familiarize you with how numbers are used in AutomationDirect PLCs. The information you learn here applies to all our PLCs!

octal 49.832 binary
 ? 1482 BCD ?
 3A9 7 ? 3 0402 ?
 1001011011 ? ASCII
 decimal -961428 ? 1011
 -300124 177 A 72B ?
 hexadecimal

As any good computer does, PLCs store and manipulate numbers in binary form: just ones and zeros. So why do we have to deal with numbers in so many different forms? Numbers have meaning, and some *representations* are more convenient than others for particular purposes. Sometimes we use numbers to represent a size or amount of something. Other numbers refer to locations or addresses, or to time. In science we attach engineering units to numbers to give a particular meaning.

PLC Resources

PLCs offer a fixed amount of resources, depending on the model and configuration. We use the word “resources” to include variable memory (V-memory), I/O points, timers, counters, etc. Most modular PLCs allow you to add I/O points in groups of eight. In fact, all the resources of our PLCs are counted in octal. It's easier for computers to count in groups of eight than ten, because eight is an even power of 2.

Octal means simply counting in groups of eight things at a time. In the figure to the right, there are eight circles. The quantity in decimal is “8”, but in octal it is “10” (8 and 9 are not valid in octal). In octal, “10” means 1 group of 8 plus 0 (no individuals).

Decimal	1	2	3	4	5	6	7	8
	●	●	●	●	●	●	●	●
Octal	1	2	3	4	5	6	7	10

In the figure below, we have two groups of eight circles. Counting in octal we have “20” items, meaning 2 groups of eight, plus 0 individuals. Don't say “twenty”, say “two-zero octal”. This makes a clear distinction between number systems.

Decimal	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16
	●	●	●	●	●	●	●	●	●	●	●	●	●	●	●	●
Octal	1	2	3	4	5	6	7	10	11	12	13	14	15	16	17	20

After *counting* PLC resources, it's time to *access* PLC resources (there's a difference). The CPU instruction set accesses resources of the PLC using octal addresses. Octal addresses are the same as octal quantities, except they start counting at zero. The number zero is significant to a computer, so we don't skip it.

Our circles are in an array of square containers to the right. To access a resource, our PLC instruction will address its location using the octal references shown. If these were counters, “CT14” would access the black circle location.

X=	0	1	2	3	4	5	6	7
X	●	●	●	●	●	●	●	●
1 X	●	●	●	●	●	●	●	●
2 X	●	●	●	●	●	●	●	●

V-Memory

Variable memory (called “V-memory”) stores data for the ladder program and for configuration settings. V-memory locations and V-memory addresses are the same thing, and are numbered in octal. For example, V2073 is a valid location, while V1983 is not valid (“9” and “8” are not valid octal digits).

Each V-memory location is one data word wide, meaning 16 bits. For configuration registers, our manuals will show each bit of a V-memory word. The least significant bit (LSB) will be on the right, and the most significant bit (MSB) on the left. We use the word “significant”, referring to the relative binary weighting of the bits.

V-memory address (octal)	V-memory data (binary)																
	MSB															LSB	
V2017		0	1	0	0	1	1	1	0	0	0	1	0	1	0	0	1

V-memory data is 16-bit binary, but we rarely program the data registers one bit at a time. We use instructions or viewing tools that let us work with binary, decimal, octal, and hexadecimal numbers. All these are converted and stored as binary for us.

A frequently-asked question is “How do I tell if a number is binary, octal, BCD, or hex”? The answer is that we usually cannot tell just by looking at the data... but it does not really matter. What matters is: the source or mechanism which writes data into a V-memory location and the thing which later reads it must both use the same data type (i.e., octal, hex, binary, or whatever). The V-memory location is just a storage box... that’s all. It does not convert or move the data on its own.

Binary-Coded Decimal Numbers

Since humans naturally count in decimal (10 fingers, 10 toes), we prefer to enter and view PLC data in decimal as well (via operator interfaces). However, computers are more efficient in using pure binary numbers. A compromise solution between the two is Binary-Coded Decimal (BCD) representation. A BCD digit ranges from 0 to 9, and is stored as four binary bits (a nibble). This permits each V-memory location to store four BCD digits, with a range of decimal numbers from 0000 to 9999.

BCD number	4	9	3	6
	8 4 2 1	8 4 2 1	8 4 2 1	8 4 2 1
V-memory storage	0 1 0 0	1 0 0 1	0 0 1 1	0 1 1 0

In a pure binary sense, a 16-bit word represents numbers from 0 to 65535. In storing BCD numbers, the range is reduced to 0 to 9999. Many math instructions use BCD data, and **DirectSOFT32** and the handheld programmer allow us to enter and view data in BCD. Special RLL instructions convert from BCD to binary, or visa-versa.

Hexadecimal Numbers

Hexadecimal numbers are similar to BCD numbers, except they utilize all possible binary values in each 4-bit digit. They are base-16 numbers so we need 16 different digits. To extend our decimal digits 0 through 9, we use A through F as shown.

Decimal	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
Hexadecimal	0	1	2	3	4	5	6	7	8	9	A	B	C	D	E	F

A 4-digit hexadecimal number can represent all 65536 values in a V-memory word. The range is from 0000 to FFFF (hex). PLCs often need this full range for sensor data, etc. Hexadecimal is just a convenient way for humans to view full binary data.

Hexadecimal number	A	7	F	4
V-memory storage	1 0 1 0	0 1 1 1	1 1 1 1	0 1 0 0

Memory Map

With any PLC system, you generally have many different types of information to process. This includes input device status, output device status, various timing elements, parts counts, etc. It is important to understand how the system represents and stores the various types of data. For example, you need to know how the system identifies input points, output points, data words, etc. The following paragraphs discuss the various memory types used in the DL405 CPUs. Memory maps for all DL405 CPUs follow the memory descriptions.

Octal Numbering System

All memory locations or areas are numbered in Octal (base 8). The diagram shows how the octal numbering system works for the discrete input points. Notice the octal system does not contain any numbers with the digits 8 or 9.

Refer to the previous section on PLC Numbering Systems for more on octal numbering.

X0 X1 X2 X3 X4 X5 X6 X7

X10 X11 X12 X13 X14 X15 X16 X17

Discrete and Word Locations

As you examine the different memory types, you'll notice two types of memory in the DL405, discrete and word memory. Discrete memory is one bit that can be either a 1 or a 0. Word memory is referred to as V memory (variable) and is a 16-bit location normally used to manipulate data/numbers, store data/numbers, etc.

Some information is automatically stored in V memory. For example, the timer current values are stored in V memory.

Discrete – On or Off, 1 bit

Word Locations – 16 bits

0 1 0 1 0 0 0 0 0 1 0 0 1 0 1

V Memory Locations for Discrete Memory Areas

The discrete memory area is for inputs, outputs, control relays, special relays, stages, global relays, timer status bits and counter status bits. However, you can also access the bit data types as a V-memory word. Each V-memory location contains 16 consecutive discrete locations. For example, the following diagram shows how the X input points are mapped into V-memory locations.

16 Discrete (X) Input Points

These discrete memory areas and the corresponding V memory locations are listed in the Memory Map tables for the DL430, DL440, and DL450 CPUs in this chapter.

Input Points (X Data Type)

The discrete input points are noted by an X data type. Refer to the memory maps for the number of discrete input points for your CPU type. In this example, the output point Y0 will energize when input X0 turns on.

Output Points (Y Data Type)

The discrete output points are noted by a Y data type. Refer to the memory maps for the number of discrete input points for your CPU type. In this example, output point Y1 will energize when input X1 turns on.

Control Relays (C Data Type)

Control relays are discrete bits normally used to control the user program. The control relays do not represent a real world device, that is, they cannot be physically tied to switches, output coils, etc. They are internal to the CPU. Because of this, control relays can be programmed as discrete inputs or discrete outputs. These locations are used in programming the discrete memory locations (C) or the corresponding word location which contains 16 consecutive discrete locations.

In this example, memory location C5 will energize when input X10 turns on. The second rung shows a simple example of how to use a control relay as an input.

Timers and Timer Status Bits (T Data type)

The amount of timers available depends on the model of CPU you are using. The tables at the end of this section provide the amount of timers in each DL405 CPU type. Regardless of the number of timers, you have access to timer status bits that reflect the relationship between the current value and the preset value of a specified timer. The timer status bit will be on when the current value is equal or greater than the preset value of a corresponding timer.

When input X0 turns on, timer T1 will start. When the timer reaches the preset of 3 seconds (K of 30) timer status contact T1 turns on. When T1 turns on, output Y12 energizes.

NOTE: Some timers and counters use one V-memory register, and other types require two V-memory registers. See the instruction descriptions in Chapter 5.

Timer Current Values (V Data Type)

Some information is automatically stored in V memory, such as the current values associated with timers. For example, V0 holds the current value for Timer 0, V1 holds the current value for Timer 1, etc. These are 4-digit BCD values.

The primary reason for this is programming flexibility. The example shows how you can use relational contacts to monitor several time intervals from a single timer.

Counters and Counter Status Bits (CT Data type)

You have access to counter status bits that reflect the relationship between the current value and the preset value of a specified counter. The counter status bit will be on when the current value is equal or greater than the preset value of a corresponding counter.

Each time contact X0 transitions from off to on, the counter increments by one. (If X1 comes on, the counter is reset to zero.) When the counter reaches the preset of 10 counts (K of 10) counter status contact CT3 turns on. When CT3 turns on, output Y12 turns on.

Counter Current Values (V Data Type)

Just like the timers, the counter current values are also automatically stored in V memory. For example, V1000 holds the current value for Counter CT0, V1001 holds the current value for Counter CT1, etc. These are 4-digit BCD values.

The primary reason for this is programming flexibility. The example shows how you can use relational contacts to monitor the counter values.

Word Memory (V Data Type)

Word memory is referred to as V memory (variable) and is a 16-bit location normally used to manipulate data/numbers, store data/numbers, etc.

Some information is automatically stored in V memory. For example, the timer current values are stored in V memory.

The example shows how a four-digit BCD constant is loaded into the accumulator and then stored in a V-memory location.

Word Locations – 16 bits

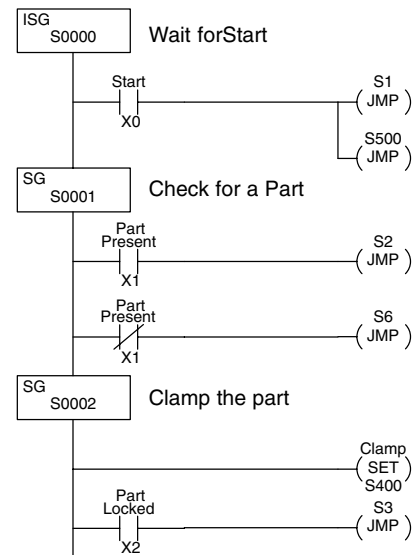

Stages (S Data type)

Stages are used in RLL^{PLUS} programs to create a structured program, similar to a flowchart. Each program stage denotes a program segment. When the program segment, or stage, is active, the logic within that segment is executed. If the stage is off, or inactive, the logic is not executed and the CPU skips to the next active stage. (See Chapter 7 for a more detailed description of RLL^{PLUS} programming.)

Each stage also has a discrete status bit that can be used as an input to indicate whether the stage is active or inactive. If the stage is active, then the status bit is on. If the stage is inactive, then the status bit is off. This status bit can also be turned on or off by other instructions, such as the SET or RESET instructions. This allows you to easily control stages throughout the program.

Ladder Representation

Special Relays (SP Data Type)

Special relays are discrete memory locations with pre-defined functionality. There are many different types of special relays. For example, some aid in program development, others provide system operating status information, etc. Appendix D provides a complete listing of the special relays.

In this example, control relay C10 will energize for 50 ms and de-energize for 50 ms because SP5 is a pre-defined relay that will be on for 50 ms and off for 50 ms.

Remote I/O Points (GX Data Type)

Remote I/O points are represented by global relays. They are generally used only to control remote I/O, but they can be used as normal control relays when remote I/O is not used in the system. You should notice the same data type, GX, is used for both the remote input and remote output points. There are setup routines that must be placed in your application program to designate which locations are inputs and which are outputs. (The DL405 Remote and Slice I/O Modules manual provides the details.)

In this example, memory location GX0 represents an output point and memory location GX10 represents an input point.

System Parameters (V Data Type) Many system parameters, such as error codes, are automatically stored in pre-defined V-memory locations. These memory locations store clock / calendar information, error codes and other types of system setup information.

Remote I/O Bit Map

This table provides a listing of the individual remote I/O points associated with each V-memory address bit. The DL430 and DL440 CPUs use the GX point type for both remote input and output point types. The DL450 CPU has the additional GY point type for use as remote output point references.

DL430 / DL440 / DL450 Remote I/O (GX) and (GY) Points																GX Address	GY Address (DL450)
MSB	17	16	15	14	13	12	11	10	7	6	5	4	3	2	1	0
